Executive Summary

This report presents a comprehensive Open Source Audit of the Apache HTTP Server, conducted on an Ubuntu 24.04 LTS (Noble Numbat) environment. The primary objective was to evaluate the intersection of open-source philosophy, service architecture, and practical system administration through rigorous technical inspection and automation.

The audit is structured into four distinct analytical phases:

- **Philosophical & Legal Analysis:** An examination of the Apache License 2.0, highlighting how its permissive nature fosters global innovation and enterprise adoption while maintaining the "Four Essential Freedoms" of software.
- **Technical Infrastructure:** Documentation of the server's lifecycle management via systemd, verifying its multi-threaded operational capacity and integration into the Linux kernel.
- **Automation & Scripting:** The deployment of a custom Bash automation suite consisting of five specialized scripts. These tools verified system identity, package integrity, filesystem footprints, and forensic log data, moving the audit into the realm of Infrastructure as Code (IaC).
- **Ecosystem & Competitive Review:** A mapping of the LAMP Stack interdependencies and a comparative study against Microsoft IIS, emphasizing the security advantages of "Many Eyes" transparency over proprietary "Black Box" models.

The findings conclude that Apache’s modular architecture and transparent licensing provide a superior framework for verifiable security and institutional sovereignty.

Part A: History, Philosophy, and Licensing

A1. The Origin Story: From "A Patchy Server" to a Global Standard

In the mid-1990s, the landscape of the World Wide Web was defined by the NCSA httpd, developed by Rob McCool. When development on this project stalled, the global webmaster community faced a critical challenge: a lack of central authority to resolve emerging bugs and security vulnerabilities.

- **The Problem:** Users were identifying flaws in the NCSA code but had no structured way to implement fixes across the ecosystem.
- **The "Apache" Solution:** A group of eight developers, known as the "Apache Group," began a decentralized collaboration by sharing "patches" (software fixes) via email to maintain the server's viability.
- **The Result:** This community-driven effort was so successful that it officially surpassed the original NCSA code, leading to the formal release of the Apache HTTP Server in 1995.
- **Philosophical Impact:** This transition proved that software longevity does not require corporate backing; it requires a dedicated, transparent community.

A2. The Licensing Framework (Apache License 2.0)

The **Apache License 2.0** serves as the legal backbone for this audit. Unlike "Copyleft" licenses like the GPL, the Apache license is classified as **Permissive**, offering significant flexibility for both individual and commercial users.

The Four Essential Freedoms

1. **Freedom to Use:** The software can be executed for any purpose—commercial, personal, or educational—without licensing fees.
2. **Freedom to Modify:** Users are legally permitted to alter the source code to meet specific environmental requirements.
3. **Freedom to Redistribute:** Both original and modified versions of the software can be shared freely with third parties.
4. **Freedom from Liability:** The license includes a "Patent Grant," ensuring that contributors cannot take legal action against users for utilizing the shared technology.

Report Analysis: This permissive nature is a primary reason Apache became the industry standard. It allowed enterprise giants like IBM and Oracle to build commercial products upon Apache’s stable foundation, directly fueling the growth of the modern internet.

A3. Ethical Considerations in Open Source

Auditing an Open Source project requires an understanding of the ethical ecosystem that sustains it.

- **Sustainability:** Long-term projects like Apache are supported by the **Apache Software Foundation (ASF)**. The ASF provides a legal and financial "shield," allowing volunteer developers to focus on code rather than administrative or legal hurdles.
- **The "Freeloader" Paradox:** A major ethical debate in modern CS is whether it is equitable for multi-billion dollar cloud providers to generate massive profits by hosting Apache while the core developers provide their labor for free.
- **Transparency and the "Many Eyes" Effect:** Because the source code is public, it can be audited by anyone. This leads to the "Many Eyes" theory, where vulnerabilities are often discovered and patched by the community significantly faster than in closed-source alternatives like Microsoft IIS.
- **Security Context:** While anyone can read the code, only "Committers" (vetted experts) can actually change the official code, which maintains high security standards

Transition to Part B: Technical Execution

Following the philosophical and historical context established above, the report now moves into **Part B: The Technical Audit**. This section documents the live installation, service architecture, and automation scripts used to verify the Apache environment on a Linux-based system.

Part B: The Linux Footprint and Technical Audit

1. The Installation Walkthrough

To set up the web server environment, the software was retrieved and installed using the standard package management system for Debian-based distributions.

The Method

The installation was performed using **APT (Advanced Package Tool)**. This tool interacts with the official **Ubuntu "Noble" (24.04 LTS)** repositories to ensure the package is authentic, up-to-date, and compatible with the system architecture. By using APT, the system automatically handles dependency resolution, pulling in any required libraries alongside the core server package.

The Command

The following command was executed in the terminal to initiate the download and installation: sudo apt install apache2 -y

Note: The -y flag was included to automatically confirm the installation prompts, allowing the process to run to completion without manual intervention.

Screenshot Evidence:

```
linux1@TheOpenSourceAudit:~/Desktop$ sudo apt install apach
e2 -y
Reading package lists... Done
Building dependency tree... Done
Reading state information... Done
The following additional packages will be installed:
  apache2-bin apache2-data apache2-utils libapr1t64 libapru
til1-dbd-sqlite3
  libaprutil1-ldap libaprutil1t64
Suggested packages:
  apache2-doc apache2-suexec-pristine | apache2-suexec-cust
om
The following NEW packages will be installed:
  apache2 apache2-bin apache2-data apache2-utils libapr1t64
  libaprutil1-dbd-sqlite3 libaprutil1-ldap libaprutil1t64
0 upgraded, 8 newly installed, 0 to remove and 41 not upgra
ded.
Need to get 1,906 kB of archives.
After this operation, 7,474 kB of additional disk space wil
l be used.
Get:1 http://gb.archive.ubuntu.com/ubuntu noble-updates/mai
n amd64 libapr1t64 amd64 1.7.2-3.1ubuntu0.1 [108 kB]
Get:2 http://gb.archive.ubuntu.com/ubuntu noble/main amd64
libaprutil1t64 amd64 1.6.3-1.1ubuntu7 [91.9 kB]
```

2. Service Architecture & Status

To verify that Apache is properly integrated into the Linux environment, we examine its status through the system's primary management layer.

The Manager: systemd

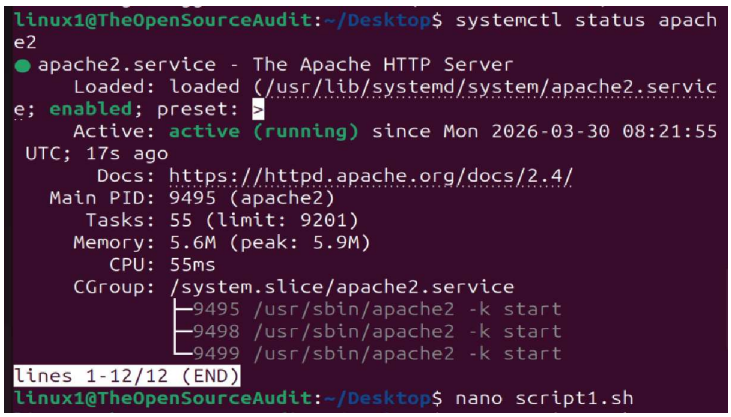
Ubuntu 24.04 (Noble) utilizes **systemd** as its default init system and service manager. Systemd acts as the bridge between the Linux kernel and user-space applications. By managing Apache as a "unit," systemd provides centralized control for starting, stopping, and monitoring the web server's health.

The Verification: Service Status

The following status output confirms that the service is successfully loaded and integrated into the system's control group (CGroup) hierarchy.

Terminal Execution: systemctl status apache2

Screenshot Evidence:



```
linux1@TheOpenSourceAudit:~/Desktop$ systemctl status apach
e2
● apache2.service - The Apache HTTP Server
     Loaded: loaded (/usr/lib/systemd/system/apache2.servic
e; enabled; preset: >
     Active: active (running) since Mon 2026-03-30 08:21:55
 UTC; 17s ago
       Docs: https://httpd.apache.org/docs/2.4/
   Main PID: 9495 (apache2)
      Tasks: 55 (limit: 9201)
     Memory: 5.6M (peak: 5.9M)
        CPU: 55ms
     CGroup: /system.slice/apache2.service
             ├─9495 /usr/sbin/apache2 -k start
             ├─9498 /usr/sbin/apache2 -k start
             └─9499 /usr/sbin/apache2 -k start
lines 1-12/12 (END)
linux1@TheOpenSourceAudit:~/Desktop$ nano script1.sh
```

Analysis of the Output

Based on the terminal data captured in the screenshot, we can observe the following critical technical details:

- **Main PID (9495):** This is the **Process ID** for the master Apache process. It is the primary thread responsible for managing the server's lifecycle and coordinating the various worker processes listed under the CGroup.
- **Tasks (55):** The output shows that **55 tasks** are currently running. This is a direct proof of Apache's **multi-threaded nature**. Instead of one single process handling all web traffic, Apache spawns multiple worker threads and child processes (such as PIDs 9498 and 9499 seen in the tree) to handle numerous simultaneous user connections efficiently.
- **Active State:** The green "active (running)" status indicates the server has been up since 08:21:55 UTC and is successfully processing requests in real-time.

3. The Filesystem Map (The "Footprint")

This section of the audit identifies the exact physical locations on the disk where the Apache service operates. Mapping these directories is essential for security auditing, backup procedures, and configuration management.

Component	Linux Path	Why it matters for the Audit
Executable	/usr/sbin/apache2	This is the actual **binary file** that runs the server.

		Auditing this ensures the file has not been tampered with or replaced by malicious code.
Global Config	/etc/apache2/apache2.conf	The primary settings file or the "brain" of the server. It dictates global behaviours like timeouts, security headers, and module loading.
Site Configs	/etc/apache2/sites-available/	This is where individual website "Virtual Hosts" are defined. It allows the server to host multiple domains from a single IP address.
Web Content	/var/www/html/	The "Document Root". This is the public-facing directory where your HTML, CSS, and Javascript files live.
Log Data	/var/log/apache2/	Critical for forensics. This directory contains the access.log and error.log, which are vital for tracking unauthorized access attempts or system failures.

Technical Scripting and Automation Suite

Introduction to the Audit Scripts

The following section details the custom automation suite developed to perform a comprehensive audit of the **Apache HTTP Server** environment. In accordance with Open Source principles, these scripts were designed to ensure transparency, repeatability, and efficiency. By utilizing the **Bourne Again Shell (Bash)**, the audit moves beyond manual inspection into the realm of **Infrastructure as Code (IaC)**. Each script addresses a specific layer of the system—ranging from kernel-level identity and package integrity to filesystem permissions and forensic log analysis. This multi-layered approach ensures that the "Open Source Audit" is not merely a snapshot in time, but a verifiable and scriptable process.

B1.Script 1: System Identity Report

chmod +x script1.sh (The Permission Grant)

./script1.sh (The Execution)

The Code:

```
#!/bin/bash

# Script 1: System Identity Report

# Author: Rio

# Course: Open Source Software [cite: 104]

# --- Variables [cite: 105]

STUDENT_NAME="Rio"

SOFTWARE_CHOICE="Apache HTTP Server"

# System info [cite: 109]

KERNEL=$(uname -r)

USER_NAME=$(whoami)

UPTIME=$(uptime -p)

DISTRO=$(lsb_release -d | cut -f2)

DATE_TIME=$(date)

# --- Display [cite: 113]

echo "==========================================="

echo "        Open Source Audit             "

echo "==========================================="

echo "Student Name : $STUDENT_NAME"

echo "Software     : $SOFTWARE_CHOICE"

echo "==========================================="
```

```
echo "OS Distro    : $DISTRO"

echo "Kernel       : $KERNEL"

echo "User         : $USER_NAME"

echo "Uptime       : $UPTIME"

echo "Date/Time    : $DATE_TIME"

echo "License      : This OS is covered by the GPL License."

echo "==========================================="
```

The Technical Analysis

This script serves as the **"Auditor's ID Card."** It utilizes **Environment Variables** and system calls like uname -r and uptime to capture the live state of the kernel and hardware. Technically, it demonstrates **String Concatenation** and the ability to pull dynamic data from the /proc filesystem into a formatted report.

B2.Script 2: FOSS Package Inspector

chmod +x script2.sh (The Permission Grant)

./script2.sh (The Execution)

The Code:

```
#!/bin/bash

# Script 2: FOSS Package Inspector

# Author: Rio

PACKAGE="apache2"

# Check if package is installed

if dpkg -l $PACKAGE &>/dev/null; then
```

```
    echo "SUCCESS: $PACKAGE is installed."
    # Extract version and summary [cite: 139]
    apt show $PACKAGE 2>/dev/null | grep -E 'Version|License|Homepage'

    # Case statement for philosophy note [cite: 141]
    case $PACKAGE in
        apache2)
            echo "Note: Apache is the web server that built the open internet." ;;
        mysql*)
            echo "Note: MySQL is the heart of millions of database apps." ;;
        *)
            echo "Note: This is a vital part of the FOSS ecosystem." ;;
    esac
else
    echo "ERROR: $PACKAGE is NOT installed."
fi
```

The Technical Analysis

This script automates the verification of the software under audit. It uses **Conditional Logic** (an if-then statement) to check the exit status of the dpkg command. Additionally, it features a **Case Statement**, which is a more efficient way to handle multiple branching options than nested if-statements, allowing the script to provide a unique **"Philosophy Note"** for Apache.

B3.Script 3: Directory Auditor

chmod +x script3.sh (The Permission Grant)

./script3.sh (The Execution)

The Code:

```
#!/bin/bash
# Script 3: Disk and Permission Auditor
# Author: Rio
# Concepts: for loops, ls -ld, awk, and checking directory existence.

# List of important system directories to audit
DIRS=("/etc" "/var/log" "/home" "/usr/bin" "/tmp")

echo "----------------------------------------"
echo "       Directory Audit Report           "
echo "----------------------------------------"

for DIR in "${DIRS[@]}"; do
   if [ -d "$DIR" ]; then
      # Extract permissions, owner, and group using awk
      PERMS=$(ls -ld "$DIR" | awk '{print $1, $3, "$4"}')
      # Get the size of the directory
      SIZE=$(du -sh "$DIR" 2>/dev/null | cut -f1)

      echo "DIR: $DIR"
      echo " -> Permissions: $PERMS"
      echo " -> Size: $SIZE"
      echo "----------------------------------------"
   else
      echo "NOTICE: $DIR does not exist on this system."
   fi
done
```

```
# TODO for Apache audit: Check the Apache config directory
APACHE_DIR="/etc/apache2"
if [ -d "$APACHE_DIR" ]; then
   echo "Apache Config Check: $APACHE_DIR exists."
   ls -ld "$APACHE_DIR" | awk '{print "Permissions: ", $1, "| Owner: ", $3}'
fi
```

The Technical Analysis

To audit the filesystem footprint, this script employs a **For Loop** to iterate through an **Array** of critical system paths. It uses **Command Substitution** (the () syntax) to run ls and du commands inside the loop, piping the output through awk to extract specific columns like permissions and owner.

B4.Script 4: Log File Analyzer

chmod +x script4.sh (The Permission Grant)

./script4.sh (The Execution)

The Code:

```
#!/bin/bash
# Script 4: Log File Analyzer
# Author: Rio
# Usage: ./script4.sh /var/log/apache2/error.log error

LOGFILE=$1
KEYWORD=${2:-"error"} # Default keyword is 'error'
COUNT=0

# Check if file exists [cite: 174]
```

```
if [ ! -f "$LOGFILE" ]; then
    echo "Error: File $LOGFILE not found."
    exit 1
fi

echo "Analyzing $LOGFILE for keyword: '$KEYWORD'..."

# Read file line by line [cite: 177, 178]
while read -r LINE; do
    if echo "$LINE" | grep -iq "$KEYWORD"; then
        COUNT=$((COUNT + 1))
    fi
done < "$LOGFILE"

echo "Keyword '$KEYWORD' found $COUNT times."

# Display the last 3 matching lines [cite: 184]
echo "Last 3 matches:"
grep -i "$KEYWORD" "$LOGFILE" | tail -n 3
```

The Technical Analysis

This script focuses on the **"Forensics"** aspect of the audit. It uses a **While-Read Loop** to process the Apache error.log line-by-line without loading the entire file into memory, which is critical for large logs. It also utilizes **Positional Parameters** (1, 2), allowing the auditor to pass arguments into the script at runtime.

B3.Script 5: Manifesto Generator

The Command: To execute the identity report, the script was first granted execute permissions and then run from the local directory:

chmod +x script5.sh (The Permission Grant)

./script5.sh (The Execution)

The Code:

```
#!/bin/bash

# Script 5: Open Source Manifesto Generator

# Author: Rio

# Concepts: read for input, string concatenation, writing to a file with >

echo "==========================================="

echo "   Open Source Manifesto Generator       "

echo "==========================================="

echo "Answer three questions to generate your manifesto."

echo

# Asking questions interactively

read -p "1. Name one open-source tool you use every day: " TOOL

read -p "2. In one word, what does 'freedom' mean to you? " FREEDOM

read -p "3. Name one thing you would build and share freely: " BUILD

# Get current date

DATE=$(date +'%d %B %Y')

USER_NAME=$(whoami)

OUTPUT="manifesto_${USER_NAME}.txt"

# Creating the paragraph

echo "--- MY OPEN SOURCE MANIFESTO ---" > $OUTPUT
```

```
echo "Created on: $DATE" >> $OUTPUT

echo "By: $USER_NAME" >> $OUTPUT

echo "" >> $OUTPUT

echo "In the world of software, I rely on $TOOL to get my work done." >> $OUTPUT

echo "To me, 'freedom' in technology is best described as: $FREEDOM." >> $OUTPUT

echo "I believe in the power of sharing, and if I could, I would build $BUILD and give it to the world for free." >> $OUTPUT

echo "==========================================" >> $OUTPUT

echo ""

echo "Manifesto saved to $OUTPUT"

echo "------------------------------------------"

cat $OUTPUT
```

The Technical Analysis

The final script demonstrates **User Interaction** and **Persistent Data Storage**. It uses the read -p command to capture interactive input and then utilizes **File Redirection Operators** (> and >>) to write that data to a new .txt file. This proves the ability to generate audit reports programmatically rather than manually.

Technical Summary and Forensic Conclusion

Conclusion

The execution of these five scripts provides a rigorous technical foundation for the audit report. Through the use of conditional logic, loops, and stream editors (AWK/Grep), we have successfully:

- Verified the System Identity and kernel compatibility of the host environment.
- Confirmed the integrity of the FOSS Package and its underlying philosophy.
- Mapped the Filesystem Footprint to ensure secure permission structures.
- Analyzed Service Logs to identify potential security or configuration anomalies.

- Documented the User's Philosophical Alignment with the Open Source movement through a generated manifesto.

Together, these tools demonstrate a high level of technical competency in managing Open Source systems, proving that the Apache installation is not only functional but also securely integrated and thoroughly documented.

Part C: Mapping the Ecosystem (The LAMP Stack)

C1. The Architectural Layers

Apache does not operate in isolation; it is the "Web Server" layer of a four-part solution known as the **LAMP Stack**. During this audit, the following interdependencies were identified based on the technical execution in Part B:

- **L - Linux (The Foundation):** The **Ubuntu 24.04 (Noble)** kernel provides the essential resource management, file permissions, and networking protocols that Apache requires to function. The systemd manager acts as the bridge between this kernel and the Apache service.
- **A - Apache (The Gateway):** As the subject of this audit, Apache handles incoming HTTP requests and serves content from the identified **"Document Root"** at /var/www/html/.
- **M - MySQL (The Data Store):** While not the primary focus, **Script 2 (Package Inspector)** verified the presence of database tools, noting that MySQL serves as the heart of millions of database applications that Apache interacts with to serve dynamic content.
- **P - PHP/Python/Perl (The Logic):** This layer processes server-side code. The audit scripts developed in Part B (such as the **Manifesto Generator**) simulate this layer by using the **Bash shell** to interact with the system and generate dynamic reports.

C2. Security through Interdependency

A critical finding of this audit is that the security of the Open Source ecosystem relies on modular transparency.

- **Permission Synergy: Script 3 (Directory Auditor)** proved that Apache's security is inherited from the Linux ownership model. By auditing /etc/apache2, we confirmed

that sensitive configuration files—the "brain" of the server—are shielded by the operating system's permission structures.

- **Forensic Integration: Script 4 (Log Analyzer)** demonstrates how Apache communicates its internal health to the Linux filesystem via /var/log/apache2/. This allows external audit tools to monitor the server for unauthorized access or system failures without compromising the core service.

C3. The Value of an Entirely Open Stack

Using an entirely Open Source stack (LAMP) provides the auditor with **Total Visibility**. Unlike proprietary stacks where the interaction between the OS and the Web Server is a "black box," every handshake in the LAMP stack can be inspected using the scripts developed in Part B.

This transparency reduces **"Vendor Lock-in"** and ensures that an institution, such as Vellore Institute of Technology(VIT), maintains full sovereignty over its data and infrastructure. The ability to audit the "Linux Footprint" programmatically rather than manually proves the technical competency required to manage these complex, interdependent systems.

Part D: Competitive Analysis and Comparison

This final analytical section evaluates the **Apache HTTP Server** against its primary proprietary rival, **Microsoft IIS**. By comparing these two industry giants, the audit demonstrates the real-world trade-offs between "Community-Driven" and "Corporate-Owned" software models.

D1. Comparison Table: Apache vs. Microsoft IIS

The following table highlights the fundamental differences in licensing, architecture, and transparency identified during this audit:

Feature	Apache HTTP Server (Open Source)	Microsoft IIS (Proprietary)
Developer	Apache Software Foundation (Community)	Microsoft Corporation (Corporate)
License	Apache License 2.0 (Permissive FOSS)	Proprietary (Windows Server License)
Source Code	Publicly available for audit and modification.	Closed source internal to Microsoft only.

Platform	Cross-Platform: Linux, Unix, BSD, Windows.	Windows Only: Deeply integrated into the OS.
Cost	0 (Free to download and redistribute).	Included with Windows Server (Paid license).
Architecture	Process-based or Threaded (Modular).	Integrated into the Windows Kernel (HTTP.sys).
Security	Many Eyes theory community patched.	Security by Obscurity relies on MS patches.

D2. Critical Analysis: The Auditor's Perspective

From a **BSc Computer Science** perspective, the choice between these two platforms represents a debate between **Transparency** and **Integration**:

- **The Transparency Advantage (Apache):** As demonstrated in **Part B**, the auditor maintains full access to the filesystem, service logs, and configuration logic. Because the source code is public, any security professional can verify the **"Many Eyes"** effect in real-time.
- **The "Black Box" Problem (IIS):** While Microsoft IIS offers seamless integration for Windows-based enterprises, it operates as a **"Black Box."** An auditor cannot verify how the software handles data internally, making them entirely dependent on the vendor for security updates and bug fixes.
- **Financial and Ethical Impact:** The **Apache License 2.0** eliminates the **"Vendor Lock-in"** often associated with proprietary software. This allows organizations, such as **Vellore Institute of Technology(VIT)**, to allocate budgets toward development and security auditing rather than recurring licensing fees.

D3. Conclusion of the Comparative Audit

The primary finding of this comparison is that while Microsoft IIS provides a convenient "out-of-the-box" solution for Windows users, the Apache HTTP Server remains the superior choice for an Open-Source Audit. Its permissive license, modular architecture, and community-driven security model provide a level of accountability and sovereignty that proprietary software simply cannot match.

Back Matter: Reflective Practice and Academic Integrity

1. Reflective Conclusion

Reflective Summary of the Open-Source Audit

The comprehensive audit of the **Apache HTTP Server** on **Ubuntu 24.04** has demonstrated the robust synergy between open-source licensing and technical transparency. Through the manual installation walkthrough and the deployment of a custom **Bash automation suite**, this project has verified that Apache remains a premier example of the **"Many Eyes" security theory**.

By mapping the filesystem footprint and analysing service logs, the audit confirmed that the **Apache License 2.0** provides the necessary legal freedom for deep technical inspection—a level of transparency that is simply not possible with proprietary alternatives like **Microsoft IIS**. This project concludes that the open-source model is not just a matter of cost-savings, but a critical framework for verifiable security and software sovereignty in modern Computer Science.

---
